ABSTRACT

With the development of information technology, computers have gradually integrated into our lives, but the computer user interface is often uncomfortable, causing various physical problems, especially repetitive strain injuries. In order to understand the effectiveness of the mouse pad and mouse combination in reducing the risk of repetitive strain injuries, this study used a self-report questionnaire to evaluate the use of different types of mouse pads and mice. Through experimental measurement results, the separation of the mouse pad and mouse is a better alternative to alleviate the pressure, reducing harm, and letting the computer user accept the habit of using a wrist support mouse, thereby reducing the chance of occurrence.

Keywords : wrist pad、EMG、rate of perceived exertion、Human Factors Engineering、Occupational injury
